

# Perl

---

Perl = **P**ractical **E**xtraction and **R**eport **L**anguage

Developed by Larry Wall (late 80's) as a replacement for `awk`.

Has grown to become a replacement for `awk`, `sed`, `grep`, other filters, shell scripts, C programs, ... (i.e. "kitchen sink").

An extremely useful tool to know because it:

- runs on Unix variants (Linux/Android/OSX/IOS/..), Windows/DOS variants, Plan 9, OS2, OS390, VMS..
- very widely used for complex scripting tasks
- has standard libraries for many applications (Web/CGI, DB, ...)

Perl has been influential: PHP, Python, Ruby, ... even Java (interpreted)

Some of the language design principles for Perl:

- make it easy/concise to express common idioms
- provide many different ways to express the same thing
- use defaults where every possible
- exploit powerful concise syntax & accept ambiguity/obscurity in some cases
- create a large language that users will learn subsets of

Many of these conflict with design principles of languages for teaching.

# Perl

---

So what is the end product like?

- a language which makes it easy to build useful systems
- readability can sometimes be a problem (language is too rich?)
- interpreted efficient? (although still remarkably efficient)

Summary: it's easy to write concise, powerful, obscure programs in Perl

## Reference Material

---

- *Wall, Christiansen & Orwant* , Programming Perl (3ed), O'Reilly, 2000. (Original & best Perl reference manual)
- *Schwartz, Phoenix & Foy*, Learning Perl (5ed), O'Reilly, 2008. (gentle & careful introduction to Perl)
- *Christiansen & Torkington*, Perl Cookbook (2ed), O'Reilly, 2003. (Lots and lots of interesting Perl examples)
- *Schwartz & Phoenix*, Learning Perl Objects, References, and Modules (2ed), O'Reilly, 2003. (gentle & careful introduction to parts of Perl mostly not covered in this course)
- *Schwartz, Phoenix & Foy*, Intermediate Perl (2ed), O'Reilly, 2008. (good book to read after 2041 - starts where this course finishes)
- *Sebesta*, A Little Book on Perl, Prentice Hall, 1999. (Modern, concise introduction to Perl)
- *Orwant, Hietaniemi, MacDonald*, Mastering Algorithms with Perl, O'Reilly, 1999. (Algorithms and data structures via Perl)

# Running Perl

---

Perl programs can be invoked in several ways ...

- giving the filename of the Perl program as a command line argument:

```
perl PerlCodeFile.pl
```

- giving the Perl program itself as a command line argument:

```
perl -e 'print "Hello, world\n";'
```

- using the #! notation and making the program file executable:

```
chmod 755 PerlCodeFile  
./PerlCodeFile
```

# Running Perl

---

Advisable to *always* use `-w` option.

Causes Perl to print warnings about common errors.

```
perl -w PerlCodeFile.pl  
perl -w -e 'PerlCode'
```

Can use options with `#!` `#!/usr/bin/perl -w`  
`PerlCode`

you can also get warnings via a pragma:

`use warnings;`

To catch other possible problems. Some programmers always use `strict`, others find it too annoying.

`use strict;`

## Syntax Conventions

---

Perl uses non-alphabetic characters to introduce various kinds of program entities (i.e. set a context in which to interpret identifiers).

Char	Kind	Example	Description
#	Comment	# comment	rest of line is a comment
\$	Scalar	\$count	variable containing simple value
@	Array	@counts	list of values, indexed by integers
%	Hash	%marks	set of values, indexed by <i>strings</i>
&	Subroutine	&doIt	callable Perl code (& optional)

# Syntax Conventions

---

Any unadorned identifiers are either

- names of built in (or other) functions (e.g. `chomp`, `split`)
- control-structures (e.g. `if`, `for`, `foreach`)
- literal strings (like the shell!)

The latter can be confusing to C/Java/PHP programmers e.g.

`x = abc; isthesameas x = "abc";`

# Variables

---

Perl provides these basic kinds of variable:

- *scalars* ... a single atomic value (number or string)
- *arrays* ... a list of values, indexed by number
- *hashes* ... a group of values, indexed by string

Variables do not need to be declared or initialised.

If not initialised, a scalar is the empty string (0 in a numeric context).

*Beware:* spelling mistakes in variable names, e.g:

```
print "abc=$acb\n";    rather than    print "abc=$abc\n";
```

Use warnings (-w) and easy to spell variable names.

# Variables

---

Many scalar operations have a "default source/target".  
If you don't specify an argument, variable `$_` is assumed  
This makes it

- often very convenient to write brief programs (minimal syntax)
- sometimes confusing to new users ("Where's the argument??")

`$_` performs a similar role to "it" in English text.

E.g. "The dog ran away. It ate a bone. It had lots of fun."

# Arithmetic & Logical Operators

---

Perl arithmetic and logical operators are similar to C.

Numeric: `== != < <= > >= <=>`

String: `eq ne lt le gt ge cmp`

Most C operators are present and have similar meanings, e.g:

`+ - * / % ++ -- +=`

Perl string concatenation operator: `.`

equivalent to using C's `malloc + strcat`

C `strcmp` equivalent to Perl `cmp`

## Scalars

---

Examples: `x = '123'`; `x` assigned string "123" `y = "123"`; `y` assigned string "123" `z = 123`; `z` assigned integer 123 `i = x + 1`; *x value converted to integer* `j = y + z`; *y value converted to integer* `a = x == y`; numeric compare `x, y` (true) `b = x eq y`; *string compare* `x, y` (false) `c = x.y`; concat `x, y` (explicit) `c = "xy"`; *concat* `x, y` (*interpolation*)

Note: `$c = $x $y` is invalid (Perl has no empty infix operator) (unlike predecessor languages such as awk, where `$x $y` meant string concatenation)

## Perl Truth Values

---

False: "" and '0'

True: everything else.

Be careful, subtle consequences:

False: 0.0, 0x0

True: '0.0' and "0\n"

# Scalars

---

A very common pattern for modifying scalars is: *var* = var op expression

*Compound assignments* for the most common operators allow you to write *var op = expression*

Examples: *x + = 1; increment the value of x*

*y \* = 2; double the value of y* *a. = " abc" append " abc" to a*

## Logical Operators

---

Perl has two sets of logical operators, one like C, the other like "English".

The second set has very low precedence, so can be used between statements.

Operation	Example	Meaning
And	<code>x &amp;&amp; y</code>	false if x is false, otherwise y
Or	<code>x    y</code>	true if x is true, otherwise y
Not	<code>! x</code>	true if x is not true, false otherwise
And	<code>x and y</code>	false if x is false, otherwise y
Or	<code>x or y</code>	true if x is true, otherwise y
Not	<code>not x</code>	true if x is not true, false otherwise

## Logical Operators

---

The lower precedence of or/and enables common Perl idioms.

if (!open FILE, 'i', "a.txt") die "Can't open a.txt: !";

is often replaced by Perl idiom

open FILE, 'i', "a" or die "Can't open a: !";

Note this doesn't work:

open FILE, 'i', "a" — die "Can't open a: !";

because its equivalent to:

open FILE, 'i', ("a" — die "Can't open a: !");

## Stream Handles

---

Input & output are accessed via *handles* - similar to FILE \* in C.

*line = < IN >; readnextlinefromstreamIN*

Output file handles can be used as the first argument to print:

print OUT "Andrew"; write line to stream OUT

Note: no comma after the handle

Predefined handles for stdin, stdout, stderr

STDOUT is default for print so can be omitted print STDOUT

"Enter your a number: "; *number = < STDIN >; if (number < 0) print STDERR "badnumber";*

## Opening Files

---

Handles can be explicitly attached to files via the open command:  
open DATA, 'i', 'data'; read from file data open RES, 'i', results';  
write to file results open XTRA, 'ii', stuff'; append to file stuff'

Handles can even be attached to pipelines to read/write to Unix  
commands: open DATE, "date—"; read output of date  
command open FEED, "—more"); send output through "more"

Opening a file may fail - always check:

open DATA, 'i', 'data' or die "Can't open data: !";

## Reading and Writing a File: Example

---

```
open OUT, 'i', 'a.txt' or die "Can't open a.txt:
!"; printOUT "42"; closeOUT; openIN, ' <'
, 'a.txt' or die "Can't open a.txt :!";
answer = < IN >; closeIN; print "answer"; prints 42
```

## Anonymous File Handles

---

If you supply a uninitialized variable Perl will store an anonymous file handle in it:

```
open my output, '>', 'answer' or die "Can't open..."; print output  
"42"; close output; open my input, 'i', 'answer' or die "Can't open  
..."; answer = <input; close input; print "answer"; prints 42
```

Use this approach for larger programs to avoid collision between file handle names.

## Close

---

Handles can be explicitly closed with `close(HandleName)`

- All handles closed on exit.
- Handle also closed if open done with same name  
good for lazy coders.
- Data on output streams may be not written (buffered)  
until close - hence close ASAP.

## <> give Unix Filter behavior

---

Calling <> without a file handle gets unix-filter behaviour.

- treats all command-line arguments as file names
- opens and reads from each of them in turn
- no command line arguments, then <> == <STDIN>

So this is `cat` in Perl:

Displays the contents of the files `a`, `b`, `c` on `stdout`.

## Control Structures

---

*All* single Perl statements must be terminated by a semicolon, e.g.

`x = 1; print "Hello";`

*All* statements with control structures must be enclosed in braces,

e.g. `if (x > 9999) print "xisbig";`

You don't need a semicolon after a statement group in `{ ... }`.

Statement blocks can also be used like anonymous functions.

# Function Calls

---

All Perl function calls ...

- are call by value (like C) (except scalars aliased to @\_)
- are expressions (although often ignore return value)

Notation(s) for Perl function calls: `func(arg1, arg2, ... argn)`

`func(arg1, arg2, ... argn)` `func arg1, arg2, ... argn`

## Control Structures

---

Selection is handled by `if ... elsif ... else if ( boolExpr1 ) statements1 elsif ( boolExpr2 ) statements2 ... else statementsn statement if ( expression );`

## Control Structures

---

Iteration is handled by `while`, `until`, `for`, `foreach`

- `while ( boolExpr ) statements`
- `until ( boolExpr ) statements`
- `for ( init ; boolExpr ; step ) statements`
- `foreach var (list) statements`

## Control Structures

---

Example (compute  $pow = k^n$ ):

- Method 1 ... while  $pow = i = 1$ ;  
while ( $i \leq n$ )  $pow = pow * k; i++$ ;
- Method 2 ... for  $pow = 1; for(i = 1; i \leq n; i++)$   $pow *= k$ ;
- Method 3 ... foreach  $pow = 1; foreach i (1..n)$   $pow *= k$ ;
- Method 4 ... builtin operator  $pow = k ** n$ ;

## Control Structures

---

Example (compute  $pow = k^n$ ):    Method 1 ... while  $pow = i = 1$ ;  
while ( $i \leq n$ )  $pow = pow * k; i++$ ;  
Method 2 ... for  $pow = 1; for(i = 1; i \leq n; i++) pow *= k$ ;  
Method 3 ... foreach  $pow = 1; foreach i (1..n) pow *= k$ ;  
Method 4 ... foreach  $pow = 1; foreach (1..n) pow *= k$ ;  
Method 5 ... builtin operator  $pow = k ** n$ ;

# Terminating

---

Normal termination, call: `exit 0`

The `die` function is used for abnormal termination:

- accepts a list of arguments
- concatenates them all into a single string
- appends file name and line number
- prints this string
- and then terminates the Perl interpreter

Example: `if (! -r "myFile") die "Can't read myFile:`

`!"; ordie "Can't read myFile :!" if ! -r "myFile"; or -r "myFile" or  
die "Can't read myFile: !"`

## Perl and External Commands

---

Perl is shell-like in the ease of invoking other commands/programs. Several ways of interacting with external commands/programs:

<code>'cmd';</code>	capture entire output of <i>cmd</i> as single string
<code>system "cmd"</code>	execute <i>cmd</i> and capture its exit status only
<code>open F,"cmd "</code>	collect <i>cmd</i> output by reading from a stream

## Perl and External Commands

---

External command examples: `files = 'lsd';` output captured  
`exit, $status = system "lsd";` output to stdout  
open my `files, 'r', "lsd";` output to stream while (`! eof` `files` >  
`) chomp; @fields = split; splitwords in @fields; print "Next file is " . fields[fields];`

## File Test Operators

---

Perl provides an extensive set of operators to query file information:

<code>-r, -w, -x</code>	file is readable, writeable, executable
<code>-e, -z, -s</code>	file exists, has zero size, has non-zero size
<code>-f, -d, -l</code>	file is a plain file, directory, sym link

Cf. the Unix `test` command.

Used in checking I/O operations, e.g. `-r "dataFile"` open my *data*, `<' , "dataFile"`;

## Special Variables

---

Perl defines numerous special variables to hold information about its execution environment.

These variables typically have names consisting of a single punctuation character e.g. `$!` `$@` `$#` `$$` `$%` ... (English names are also available)

The `$_` variable is particularly important:

- acts as the default location to assign result values (e.g. `<STDIN>`)
- acts as the default argument to many operations (e.g. `print`)

Careful use of `$_` can make programs concise, uncluttered.

Careless use of `$_` can make programs cryptic.

## Special Variables

---

<code>\$_</code>	default input and pattern match
<code>@ARGV</code>	list (array) of command line arguments
<code>\$0</code>	name of file containing executing Perl script (cf. shell)
<code>\$i</code>	matching string for $i^{th}$ regexp in pattern
<code>\$!</code>	last error from system call such as open
<code>\$.</code>	line number for input file stream
<code>\$/</code>	line separator, none if undefined
<code>\$\$</code>	process number of executing Perl script (cf. shell)
<code>%ENV</code>	lookup table of environment variables

## Special Variables

---

Example (echo in Perl): `for ( $i = 0$ ;  $i$  | @ARGV;  
 $i++$ )print "ARGV[ $i$ "]; print "";`  
or `foreach arg (@ARGV)print "arg "; print "";`  
or `print "@ARGV";`
